## 3.3 V to 20 V Adjustable Dual LDO with Adjustable Current Limit and 3.3 V Logic Compatible Enable Inputs

The NCV47411 is a dual integrated low dropout regulator with 100 mA per channel designed for use in harsh automotive environments. It includes wide operating temperature and input voltage ranges. The device is offered with adjustable voltage version available in 3% output voltage accuracy. It has a high peak input voltage tolerance and reverse input voltage protection. It also provides overcurrent protection, overtemperature protection and enable for control of the state of the output voltage of each channel. The integrated current sense feature provides diagnosis and system protection functionality. The current limit of the device is adjustable by resistor connected to CSO pin for each channel. CSO pin output current creates voltage drop across CSO resistor which is proportional to output current of each channel.

### Features

- Two Adjustable Outputs: (from 3.3 V to 20 V)  $\pm 3\%$  Output Voltage
- Enable Inputs (3.3 V Logic Compatible Thresholds)
- Adjustable Current Limit up to 150 mA
- Protection Features:
  - ◆ Current Limitation
  - ◆ Thermal Shutdown
  - ◆ Reverse Input Voltage
- This is a Pb-Free Device

### Typical Applications

- Audio and Infotainment System
- Instrument Cluster
- Navigation
- Satellite Radio

## DEFINITIONS

### General

All measurements are performed using short pulse low duty cycle techniques to maintain junction temperature as close as possible to ambient temperature.

### Output voltage

The output voltage parameter is defined for specific temperature, input voltage and output current values or specified over Line, Load and Temperature ranges.

### Line Regulation

The change in output voltage for a change in input voltage measured for specific output current over operating ambient temperature range.

### Load Regulation

The change in output voltage for a change in output current measured for specific input voltage over operating ambient temperature range.

### Dropout Voltage

The input to output differential at which the regulator output no longer maintains regulation against further reductions in input voltage. It is measured when the output drops 2% of  $V_{out\_nom\_n}$  below its nominal value. The junction temperature, load current, and minimum input supply requirements affect the dropout level.

### Quiescent and Disable Currents

Quiescent Current ( $I_Q$ ) is the difference between the input current (measured through the LDO input pin) and the output load current. If Enable pin is set to LOW the regulator reduces its internal bias and shuts off the output, this term is called the disable current ( $I_{DIS}$ ).

### Current Limit

Current Limit is value of output current by which output voltage drops below 90% of its nominal value.

### PSRR

Power Supply Rejection Ratio is defined as ratio of output voltage and input voltage ripple. It is measured in decibels (dB).

### Line Transient Response

Typical output voltage overshoot and undershoot response when the input voltage is excited with a given slope.

### Load Transient Response

Typical output voltage overshoot and undershoot response when the output current is excited with a given slope between low-load and high-load conditions.

### Thermal Protection

Internal thermal shutdown circuitry is provided to protect the integrated circuit in the event that the maximum junction temperature is exceeded. When activated at typically 175°C, the regulator turns off. This feature is provided to prevent failures from accidental overheating.

### Maximum Package Power Dissipation

The power dissipation level is maximum allowed power dissipation for particular package or power dissipation at which the junction temperature reaches its maximum operating value, whichever is lower.

APPLICATIONS INFORMATION

**Circuit Description**

The NCV47411 is an integrated dual low dropout regulator that provides a regulated voltage at 100 mA to each output. It is enabled with an input to the enable pin. The regulator voltage is provided by a PNP pass transistor controlled by an error amplifier with a bandgap reference, which gives it the lowest possible dropout voltage. The output current capability is 100 mA per output, and the base drive quiescent current is controlled to prevent oversaturation when the input voltage is low or when the output is overloaded. The integrated current sense feature provides diagnosis and system protection functionality. The current limit of the device is adjustable by resistor connected to CSO1,2 pin. Voltage on CSO1,2 pin is proportional to output current. The regulator is protected by both current limit and thermal shutdown. Thermal shutdown occurs above 150°C to protect the IC during overloads and extreme ambient temperatures.

**Regulator**

The error amplifier compares the reference voltage to a sample of the output voltage ( $V_{out1,2}$ ) and drives the base of a PNP series pass transistor via a buffer. The reference is a bandgap design to give it a temperature stable output. Saturation control of the PNP is a function of the load current and input voltage. Oversaturation of the output power device is prevented, and quiescent current in the ground pin is minimized.

**Regulator Stability Considerations**

The input capacitor ( $C_{in}$ ) is necessary to stabilize the input impedance to avoid voltage line influences. The output capacitor ( $C_{out1,2}$ ) helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability. The capacitor value and type should be based on cost, availability, size and temperature constraints. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures ( $-25^{\circ}C$  to  $-40^{\circ}C$ ), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer’s data sheet usually provides this information. The value for the output capacitor  $C_{out1,2}$ , shown in Figure 1 should work for most applications; see also Figure 12 for output stability at various load and Output Capacitor ESR conditions. Stable region of ESR in Figure 12 shows ESR values at which the LDO output voltage does not have any permanent oscillations at any dynamic changes of output load current. Marginal ESR is the value at which the output voltage waving is fully damped during four periods after the load change and no oscillation is further observable.

ESR characteristics were measured with ceramic capacitors and additional series resistors to emulate ESR. Low duty cycle pulse load current technique has been used

to maintain junction temperature close to ambient temperature.

**Calculating Bypass Capacitor**

If improved stability (reducing output voltage ringing during transients) is demanded, connect the bypass capacitor  $C_{b1,2}$  between Adjustable Input pin and  $V_{out1,2}$  pin according to Applications circuit at Figure 1. Parallel combination of bypass capacitor  $C_{b1,2}$  with the feedback resistor  $R_{n1}$  contributes in the device transfer function as an additional zero and affects the device loop stability, therefore its value must be optimized. Attention to the Output Capacitor value and its ESR must be paid. See also Stability in High Speed Linear LDO Regulators Application Note, AND8037/D for more information. Optimal value of bypass capacitor is given by following expression

$$C_{bn} = \frac{1}{2 \times \pi \times f_z \times R_{n1}} \text{ (F)} \quad \text{(eq. 1)}$$

where:

- $R_{n1}$  - the upper feedback resistor
- $f_z$  - the frequency of the zero added into the device transfer function by  $R_{n1}$  and  $C_{b1}$  external components.

Set the  $R_{n1}$  resistor according to output voltage requirement. Chose the  $f_z$  with regard on the output capacitance  $C_{out1,2}$ , refer to the table below.

$C_{out1,2}$ ( $\mu F$ )	10	22	47	100
$f_z$ range (kHz)	min 1.9	min 0.87	min 1.24	N/A*

\*For  $C_{out1,2} = 100 \mu F$  and higher  $C_{b1,2}$  capacitors are not needed for stability improvement.  $C_{b1,2}$  capacitors are useful for noise reduction. See electrical characteristic table.

Ceramic capacitors and its part numbers listed bellow have been used as low ESR output capacitors  $C_{out1,2}$  from the table above to define the frequency ranges of additional zero required for stability:

- GRM31CR71C106KAC7 (10  $\mu F$ , 16 V, X7R, 1206)
- GRM32ER71C226KE18 (22  $\mu F$ , 16 V, X7R, 1210)
- GRM32ER61C476ME15 (47  $\mu F$ , 16 V, X5R, 1210)
- GRM32ER60J107ME20 (100  $\mu F$ , 6.3 V, X5R, 1210)

**Enable Inputs**

An enable pin is used to turn a channel on or off. By holding the pin down to a voltage less than 0.99 V, the output of the channel will be turned off. When the voltage on the enable pin is greater than 2.31 V, the output of the channel will be enabled to power its output to the regulated output voltage. The enable pins may be connected directly to the input pin to give constant enable to the output channel.

**Setting the Output Voltage**

The output voltage range can be set between 3.3 V and 20 V. This is accomplished with an external resistor divider feeding back the voltage to the IC back to the error amplifier by the voltage adjust pin ADJ1,2. The internal reference voltage is set to a temperature stable reference ( $V_{REF1}$ ) of 1.275 V. The output voltage is calculated from the following formula. Ignoring the bias current into the ADJ1,2 pin:

$$V_{out\_nom\_n} = V_{REF1} \left( 1 + \frac{R_{n1}}{R_{n2}} \right) \quad (eq. 2)$$

Use  $R_{n2} < 50 \text{ k}\Omega$  to avoid significant voltage output errors due to ADJ1,2 bias current.

Designers should consider the tolerance of  $R_{n1}$  and  $R_{n2}$  during the design phase.

**Setting the Output Current Limit**

The output current limit can be set between 10 mA and 150 mA by external resistor  $R_{CSO1,2}$  (see Figure 1). Capacitor  $C_{CSO1,2}$  of 1  $\mu\text{F}$  in parallel with  $R_{CSO1,2}$  is required for stability of current limit control circuitry (see Figure 1).

$$V_{CSO1,2} = I_{out1,2} \left( R_{CSO1,2} \times \frac{1}{50} \right) \quad (eq. 3)$$

$$I_{LIM1,2} = \frac{50}{1} \times \frac{2.55}{R_{CSO1,2}} \quad (eq. 4)$$

$$R_{CSO1,2} = \frac{50}{1} \times \frac{2.55}{I_{LIM1,2}} \quad (eq. 5)$$

where:

- $R_{CSO1,2}$  – current limit setting resistor
- $V_{CSO1,2}$  – voltage at CSO pin proportional to  $I_{out1,2}$
- $I_{LIM1,2}$  – current limit value
- $I_{out1,2}$  – output current actual value

CSO1,2 pin provides information about output current actual value. The CSO1,2 voltage is proportional to output current according to Equation 3.

Once output current reaches its limit value ( $I_{LIM1,2}$ ) set by external resistor  $R_{CSO1,2}$  than voltage at CSO1,2 pin is typically 2.55 V. Calculations of  $I_{LIM1,2}$  or  $R_{CSO1,2}$  values can be done using equations Equations 4 and 5, respectively.

Designers should consider the tolerance of  $R_{CSO1,2}$  during the design phase.

**Thermal Considerations**

As power in the NCV47411 increases, it might become necessary to provide some thermal relief. The maximum

power dissipation supported by the device is dependent upon board design and layout. Mounting pad configuration on the PCB, the board material, and the ambient temperature affect the rate of junction temperature rise for the part. When the NCV47411 has good thermal conductivity through the PCB, the junction temperature will be relatively low with high power applications. The maximum dissipation the NCV47411 can handle is given by:

$$P_{D(MAX)} = \frac{[T_{J(MAX)} - T_A]}{R_{\theta JA}} \quad (eq. 6)$$

Since  $T_J$  is not recommended to exceed  $150^\circ\text{C}$ , then the NCV47411 soldered on  $645 \text{ mm}^2$ , 1 oz copper area, FR4 can dissipate up to 2.4 W (single layer PCB) when the ambient temperature ( $T_A$ ) is  $25^\circ\text{C}$ . See Figure 18 for  $R_{\theta JA}$  versus PCB area. The power dissipated by the NCV47411 can be calculated from the following equations:

$$P_D \approx V_{in}(I_q @ I_{out1,2}) + I_{out1}(V_{in} - V_{out1}) + I_{out2}(V_{in} - V_{out2}) \quad (eq. 7)$$

or

$$V_{in(MAX)} \approx \frac{P_{D(MAX)} + (V_{out1} \times I_{out1}) + (V_{out2} \times I_{out2})}{I_{out1} + I_{out2} + I_q} \quad (eq. 8)$$

**Figure 18. Thermal Resistance vs. PCB Copper Area**

**Figure 19. Maximum DC Output Current vs. Input to Output Voltage Differential**

Example of safe operating area (SOA) restricted by maximum DC output current per channel (both channels

loaded equally) and input to output voltage differential (both nominal output voltages are equal) in ambient temperature range from  $-40^{\circ}\text{C}$  to  $125^{\circ}\text{C}$  is shown in Figure 19. The maximum DC output current per channel is the current when the output voltage of corresponding channel has dropped 3% below its nominal output voltage without activation of thermal shutdown protection. Measurement was done in temperature chamber using double-sized PCB 3 x 3 inch (75 x 75 mm), Cu layers thickness 1 oz (35  $\mu\text{m}$ ) with copper occupying more than 90% of both sides surface.

**Hints**

$V_{in}$  and GND printed circuit board traces should be as wide as possible. When the impedance of these traces is high, there is a chance to pick up noise or cause the regulator to malfunction. Place external components, especially the output capacitor, as close as possible to the NCV47411 and make traces as short as possible. To achieve better GND potential distribution on PCB towards output resistor dividers connect not internally bonded pin No. 11 to GND plane and EPAD.

SCILLC owns the rights to a number of patents, trademarks, copyrights, trade secrets, and other intellectual property. A listing of SCILLC's product/patent coverage may be accessed at [www.onsemi.com/site/pdf/Patent-Marking.pdf](http://www.onsemi.com/site/pdf/Patent-Marking.pdf). SCILLC reserves the right to make changes without further notice to any products herein. SCILLC makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does SCILLC assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. "Typical" parameters which may be provided in SCILLC data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. SCILLC does not convey any license under its patent rights nor the rights of others. SCILLC products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the SCILLC product could create a situation where personal injury or death may occur. Should Buyer purchase or use SCILLC products for any such unintended or unauthorized application, Buyer shall indemnify and hold SCILLC and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that SCILLC was negligent regarding the design or manufacture of the part. SCILLC is an Equal Opportunity/Affirmative Action Employer. This literature is subject to all applicable copyright laws and is not for resale in any manner.
